

Chapter 3: Operating-System Structures

Process Management

- A *process* is a program in execution. A process needs certain resources, including CPU time, memory, files, and I/O devices, to accomplish its task.
- The operating system is responsible for the following activities in connection with process management.
 - ☞ Process creation and deletion.
 - ☞ process suspension and resumption.
 - ☞ Provision of mechanisms for:
 - 📄 process synchronization
 - 📄 process communication

Main-Memory Management

- Memory is a large array of words or bytes, each with its own address. It is a repository of quickly accessible data shared by the CPU and I/O devices.
- Main memory is a volatile storage device. It loses its contents in the case of system failure.
- The operating system is responsible for the following activities in connections with memory management:
 - ☞ Keep track of which parts of memory are currently being used and by whom.
 - ☞ Decide which processes to load when memory space becomes available.
 - ☞ Allocate and deallocate memory space as needed.

File Management

- A file is a collection of related information defined by its creator. Commonly, files represent programs (both source and object forms) and data.
- The operating system is responsible for the following activities in connections with file management:
 - ☞ File creation and deletion.
 - ☞ Directory creation and deletion.
 - ☞ Support of primitives for manipulating files and directories.
 - ☞ Mapping files onto secondary storage.
 - ☞ File backup on stable (nonvolatile) storage media.

I/O System Management

- The I/O system consists of:
 - ☞ A buffer-caching system
 - ☞ A general device-driver interface
 - ☞ Drivers for specific hardware devices

Secondary-Storage Management

- Since main memory (*primary storage*) is volatile and too small to accommodate all data and programs permanently, the computer system must provide *secondary storage* to back up main memory.
- Most modern computer systems use disks as the principle on-line storage medium, for both programs and data.
- The operating system is responsible for the following activities in connection with disk management:
 - ☞ Free space management
 - ☞ Storage allocation
 - ☞ Disk scheduling

Networking (Distributed Systems)

- A *distributed* system is a collection processors that do not share memory or a clock. Each processor has its own local memory.
- The processors in the system are connected through a communication network.
- Communication takes place using a *protocol*.
- A distributed system provides user access to various system resources.
- Access to a shared resource allows:
 - ☞ Computation speed-up
 - ☞ Increased data availability
 - ☞ Enhanced reliability

Protection System

- *Protection* refers to a mechanism for controlling access by programs, processes, or users to both system and user resources.
- The protection mechanism must:
 - ☞ distinguish between authorized and unauthorized usage.
 - ☞ specify the controls to be imposed.
 - ☞ provide a means of enforcement.

Command-Interpreter System

- Many commands are given to the operating system by control statements which deal with:
 - ☞ process creation and management
 - ☞ I/O handling
 - ☞ secondary-storage management
 - ☞ main-memory management
 - ☞ file-system access
 - ☞ protection
 - ☞ networking

Command-Interpreter System (Cont.)

- The program that reads and interprets control statements is called variously:

- ➡ command-line interpreter
- ➡ shell (in UNIX)

Its function is to get and execute the next command statement.

Operating System Services

- Program execution – system capability to load a program into memory and to run it.
- I/O operations – since user programs cannot execute I/O operations directly, the operating system must provide some means to perform I/O.
- File-system manipulation – program capability to read, write, create, and delete files.
- Communications – exchange of information between processes executing either on the same computer or on different systems tied together by a network. Implemented via *shared memory* or *message passing*.
- Error detection – ensure correct computing by detecting errors in the CPU and memory hardware, in I/O devices, or in user programs.

Additional Operating System Functions

Additional functions exist not for helping the user, but rather for ensuring efficient system operations.

- Resource allocation – allocating resources to multiple users or multiple jobs running at the same time.
- Accounting – keep track of and record which users use how much and what kinds of computer resources for account billing or for accumulating usage statistics.
- Protection – ensuring that all access to system resources is controlled.

System Calls

- System calls provide the interface between a running program and the operating system.
 - ☞ Generally available as assembly-language instructions.
 - ☞ Languages defined to replace assembly language for systems programming allow system calls to be made directly (e.g., C, C++)
- Three general methods are used to pass parameters between a running program and the operating system.
 - ☞ Pass parameters in *registers*.
 - ☞ Store the parameters in a table in memory, and the table address is passed as a parameter in a register.
 - ☞ *Push* (store) the parameters onto the *stack* by the program, and *pop* off the stack by operating system.

Types of System Calls

- Process control
- File management
- Device management
- Information maintenance
- Communications

System Programs

- System programs provide a convenient environment for program development and execution. They can be divided into:
 - ➡ File manipulation
 - ➡ Status information
 - ➡ File modification
 - ➡ Programming language support
 - ➡ Program loading and execution
 - ➡ Communications
 - ➡ Application programs
- Most users' view of the operation system is defined by system programs, not the actual system calls.
